

# **Siemens-Energy Gas Engines: *Important Technical Considerations in the Application of a Biogas CHP Plant***

# Content overview

**01**

**Fuel Considerations**

**02**

**Mode of Operation**

**03**

**Application of Heat**

# Fuel Considerations

## Fuel Energy

### LHV

- Energy per unit volume of gas
- Typically ranges between 590 – 650 Btu/SFC for biogas
- Extended range requires methane signal

### Methane Number

- Indicates the volatility of the fuel

## Contaminants

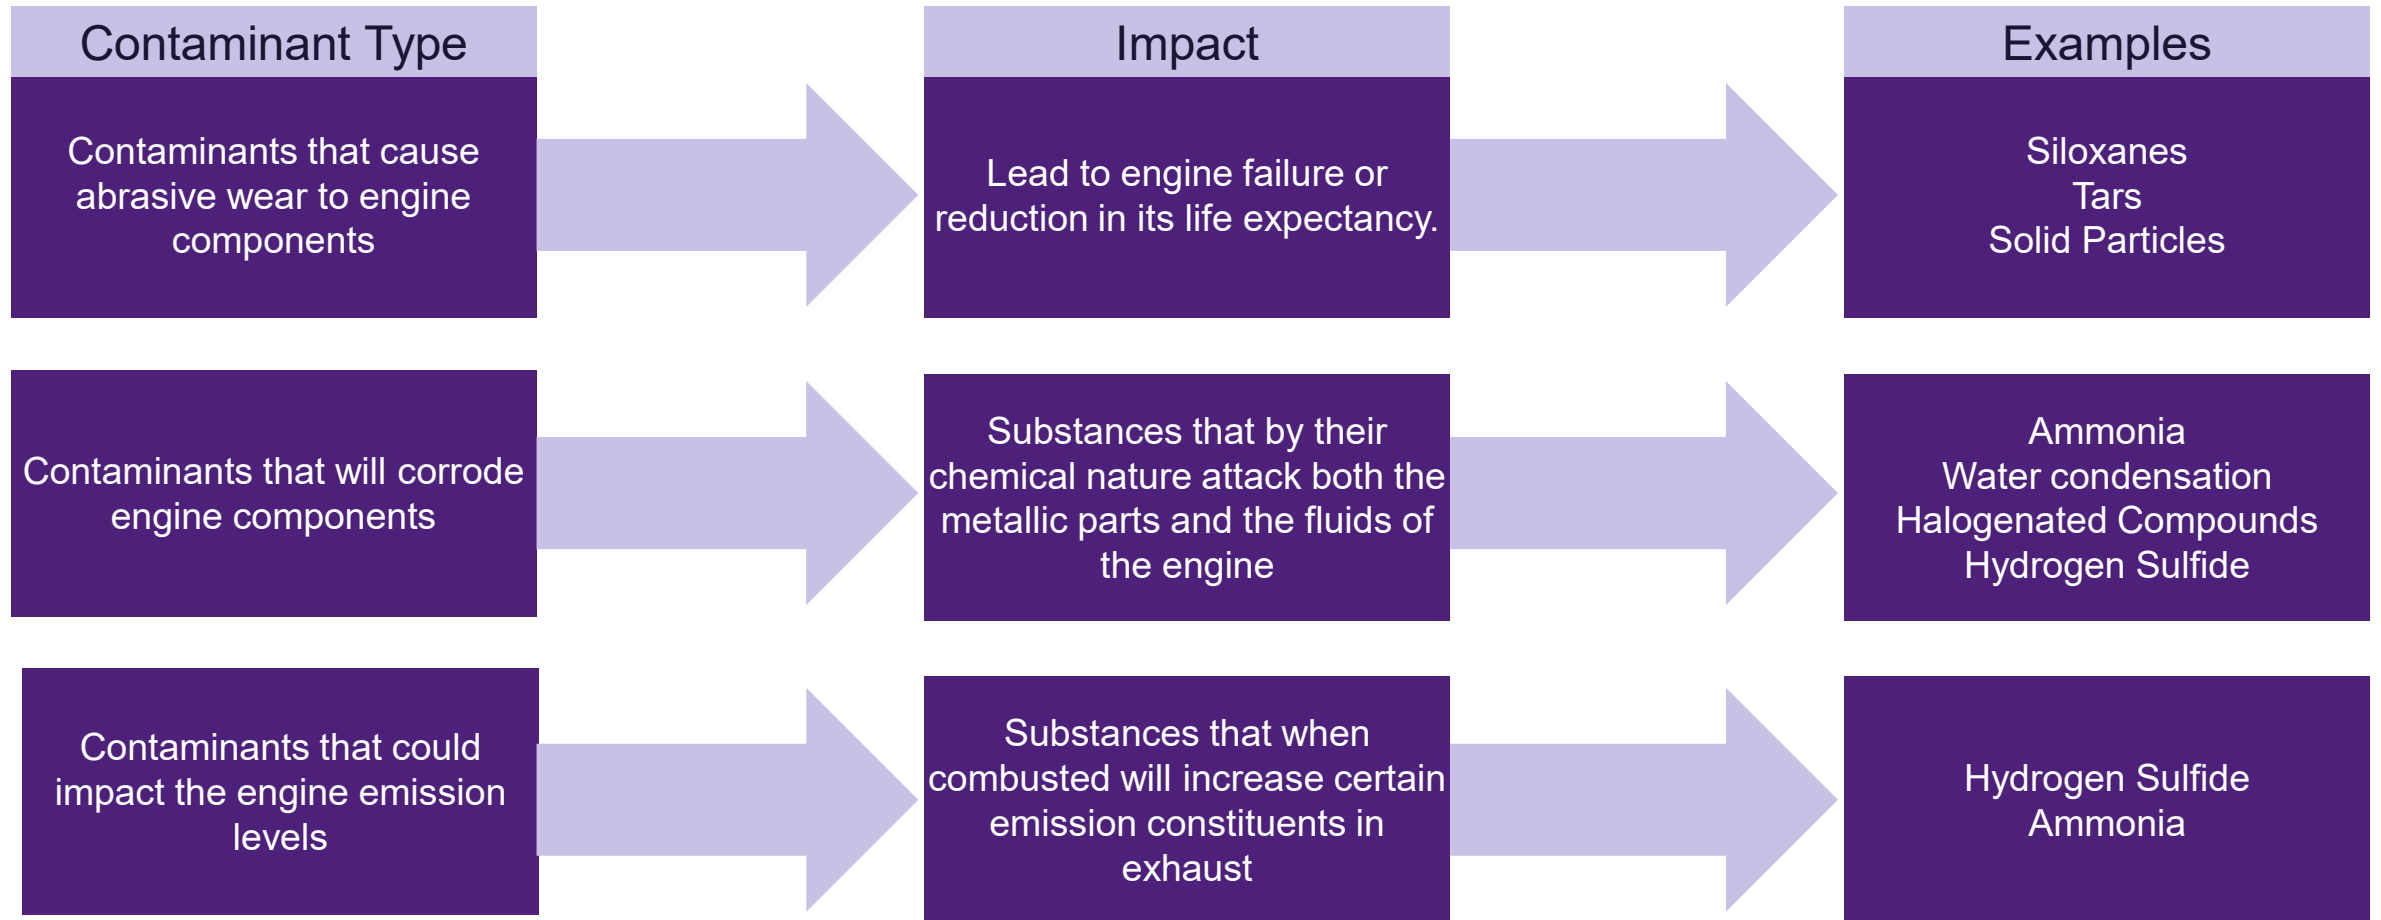

### Hydrogen Sulfide

- Attacks metallic parts of the engine
- Premature degradation of lubrication oil
- Generates sulfur oxides in exhaust
  - *Attack exhaust gas piping and can reduce catalyst life*
  - *Emissions of sulfur oxides may be limited by law*

### Silicon Compounds

- These crystalline compounds form abrasive particles in engine
- Can jam valves, pistons and other parts essential to operation
- Reduces oil properties which in turn affects engine parts

# Contaminants

# Fuel Considerations

## What is fuel blending?

Combining gaseous fuel supplies from two different and separate sources for use in a running engine while maintaining engine performance.

## Why?

To compensate for the variability in one fuel source by supplementing from a second known and reliable source.

## For Example

Waste Water Treatment Plants  
Biogas and Natural Gas

## Operating Modes:

- Mode 1: 100% Fuel A (Biogas)
- Mode 2: Fuel Blending. Blending ratio determined by algorithm or customizable through 4-20 mA signal.
  - (90 / 10 ratio)
- Mode 3: 100% Fuel B (Natural gas)

# Advantages & Benefits of Fuel Blending

Drivers	Advantage & Benefit
<b>1</b> Maximize economic benefit of the plant	<ul style="list-style-type: none"><li>• Better payback</li><li>• Maximize use of incentives</li></ul>
<b>2</b> Optimize sizing and equipment selection	<ul style="list-style-type: none"><li>• Flexibility to adapt to the required load</li><li>• Maximize the amount of energy provided from biogas</li></ul>
<b>3</b> Environmentally Responsible	<ul style="list-style-type: none"><li>• Reduces flaring</li><li>• Eliminates the need to deliver power from a remote source</li></ul>
<b>4</b> Ensures constant energy availability from CHP Plant	<ul style="list-style-type: none"><li>• Decreases likelihood boilers will need to be fired</li><li>• Helps to avoid sourcing electrical supplies from the grid</li></ul>

**Mode of Operation**

**03**

**Application of Heat**

# Application of Heat

## Power Generation

# Application of Heat

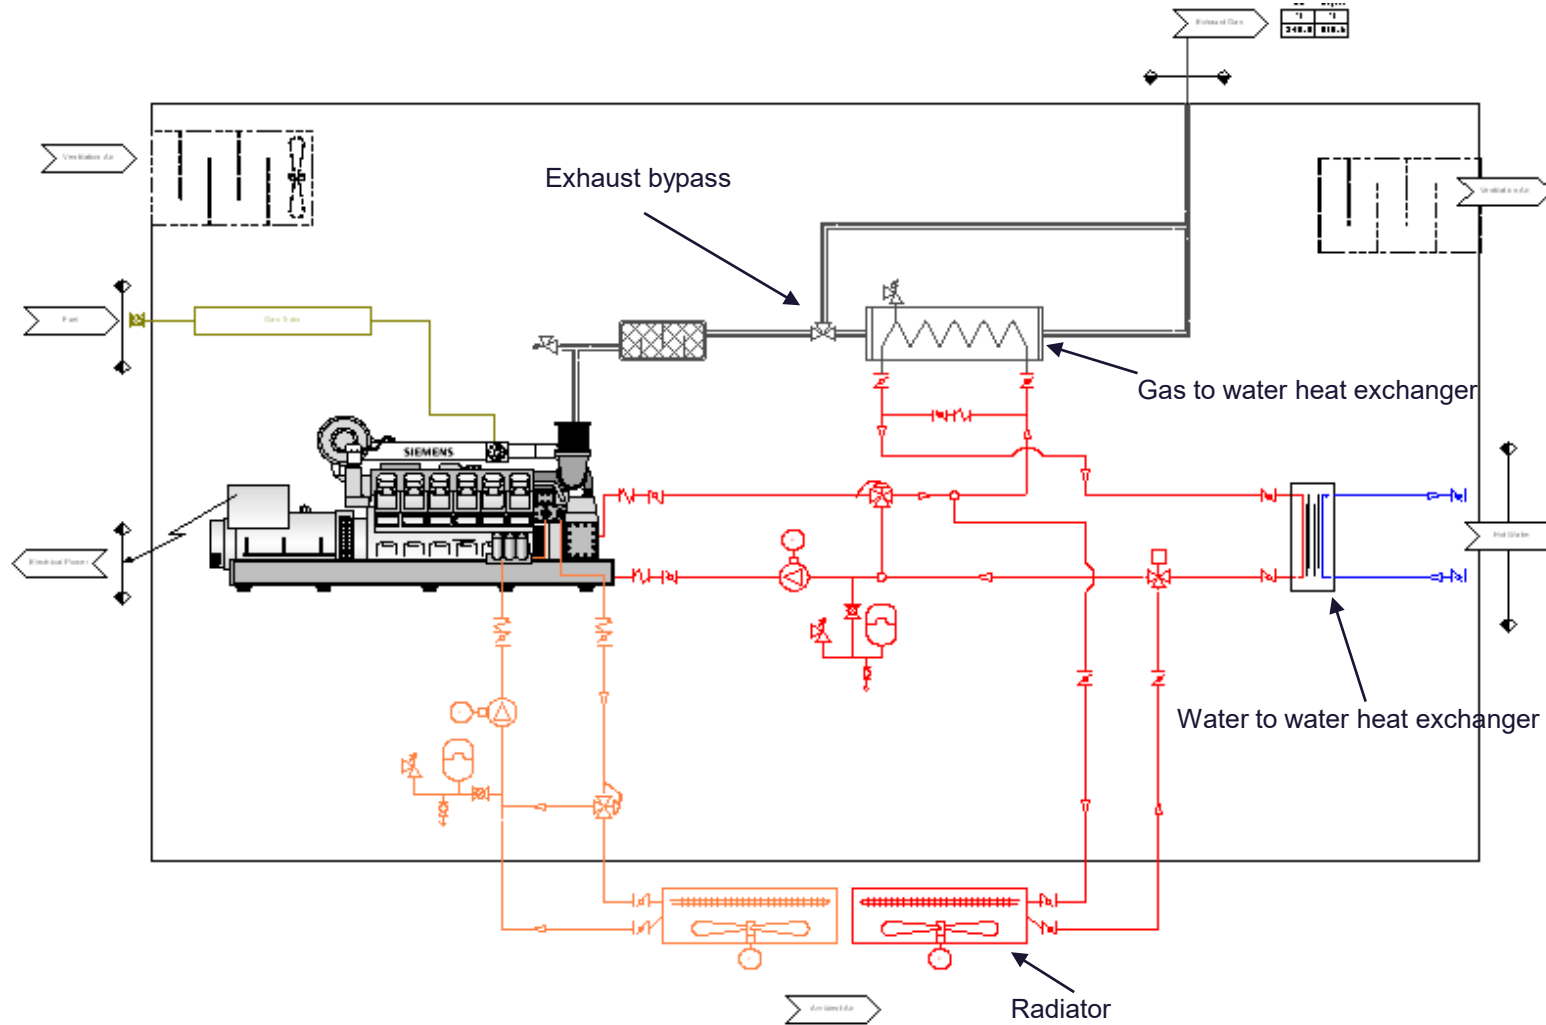

## Cogeneration

■ Energy Used    ■ Energy Not Used

# Application of Heat

## Equipment Required

### Recovery:

#### Gas to water heat exchanger

- The heat in the exhaust gases is recovered by passing through a gas-to-water heat exchanger

#### Water to water heat exchanger

- The high-grade heat of engine jacket water circuit is recovered through water-to-water heat exchanger

### Rejection:

#### Exhaust bypass

- Manages the amount of exhaust heat recovered based on site demand

#### Radiator

- Dissipates jacket water heat when not recovered by the site

# Application of Heat

## Application of Heat

### Thermal energy usage

- Steam and/or Hot Water

### Steam Applications

- Steam production possible by recovering only the exhaust heat

### Hot Water Applications

- Majority of applications using RICE are hot water (~90%)
- Typical configuration will add exhaust heat to jacket water circuit
- The temperature of the process is governed by required jacket water temperatures
- Approximate process water temperatures 185°F-190°F with this arrangement
- Some higher temp options available

# In Summary

**To realize the economic value of your cogeneration system, it is important to consider the following factor:**

- **Review you fuel**
- **Understand your mode of operation**
- **Be specific on how you are going to apply the heat**

**Take all of these into consideration and you are on the right path to a successful cogeneration application.**

Thank you!
